MEMORANDUM

TO: Council Members

FROM: John Ollis, Manager of Planning and Analysis

SUBJECT: 2021 Power Plan Draft Wholesale Electricity Price and Avoided CO₂ Emissions Rate Forecast Part 5

BACKGROUND:

Presenter: John Ollis

Summary: This presentation will continue to update the Council on the status of the 2020 wholesale electricity price forecast and avoided emissions rate study updates for the 2021 Power Plan, and the most recent response from the November 4th System Analysis Advisory Committee. Per previous discussions with the Power Committee, Staff has attempted to improve the forecast and incorporate the significant stakeholder feedback. Several additional methodological changes have been implemented relating to the modeling in AURORA. Staff will report on the current status of these studies per these changes.

Relevance: The Council periodically updates a 20-year forecast of electric power prices and avoided emissions rate studies using the AURORA model. The AURORA model dispatches all resources in the WECC generating a fundamentals-based wholesale electricity price forecast.

The study of avoided carbon dioxide production rates of the northwest power system will evaluate what the implied avoided carbon emissions rate is in the WECC and the implications for regional conservation replacing the need for that production.
Since the development of the midterm and previous avoided emissions rate study, more baseload plant retirements have been announced and further clean policies and goals have been announced. These municipal, utility and state policies/goals along with the retirements and pressures on conventional fossil fuel resources continue to fundamentally change the wholesale market dynamics in the WECC, and this updated price forecast helps Staff incorporate the effects of these changes on Mid-C market prices and the implied avoided market emission rate.

For the 2021 Power Plan, the Regional Portfolio Model will use the power prices from this study to develop electricity price futures which are used as a starting point for resource valuation in the resource strategy analysis. Additionally, the avoided market emissions rate is used in the resource strategy analysis to determine the emissions associated with reliance on the market.

Workplan: Forecast Wholesale Electricity Prices (A.6.3)

Background: The Council’s wholesale electricity price forecast is a fundamentals-based, forecast that reflects actual power system operation, relationships of supply and demand for, and transmission of electricity. In addition, underlying a wholesale electricity price forecast in this region would be an understanding of the operating characteristics of future and existing supply and demand-side resources, as well as unit commitment, ancillary services, fuel prices, hydro, wind and solar conditions. The AURORA software captures many of these characteristics of the power system well and has a periodically updated WECC database, and thus, AURORA has been the Council’s wholesale market electricity price forecasting model.

Additionally, the cost of future carbon dioxide regulation has been a significant factor in resource planning in the Pacific Northwest. To avoid making higher cost resource choices, a direct evaluation of this risk requires an estimate of the carbon dioxide emissions avoided by purchasing conservation or another resource. The Council has periodically updated this study using the AURORA model to help inform Council staff and regional stakeholder analysis.

More Info: Some of the slides for this presentation are pending on ongoing studies and recommendations from the November 4th, 2020 System Analysis Advisory Committee meeting.

Timeline – Wholesale Power Price and Market Emissions Rate Forecast

Updated price forecast per new state policies in late 2019 (presented to SAAC in Oct. and Council in Nov.)

In region demand and WECC-wide statewide policies updated mid-July 2020

Present baseline study results at the August 2020 power committee meeting

Generating resource fixed costs, fuel prices and external to the region WECC loads updated as of March 2020

Get updated guidance from SAAC about AURORA setup and methodologies for 2021 Power Plan runs

(1) Use power prices and avoided CO2e emissions rates to inform RPM of external market information.

(2) Use buildout to guide construction of GENESYS external market bins.

Follow-up meetings with SAAC/Power Committee yielded further concerns
Get A Strategy: Why a *Reasonable* WECC-Wide Build Out Matters

AURORA Buildout

Long term capital expansion for the WECC ensures that price simulations in AURORA are informed by an *adequate system* that *meets policies*.

AURORA Price Runs

Hourly market capability is needed for GENESYS to provide a *good adequacy signal for the NW* informed by changing market fundamentals.

GENESYS

Hourly analysis in GENESYS creates quarterly ARMs and ASCCs, which the RPM uses to *select an adequate resource strategy*.

RPM

Hourly WECC-wide price simulations inform *market prices* and *associated emissions* in the RPM, both can significantly impact *regional resource strategy economics*. 
Candidate *regional resource strategy* is checked in GENESYS to ensure the system is adequate and operationally feasible.

Candidate *regional resource strategy* may be checked within the context of the WECC to ensure we are consistent with policies and operational feasibility within a WECC-wide context.

Long term capital expansion for the WECC ensures that a check in AURORA is informed by an *adequate system* that *meets policies*.
Revising our Instinct for a “Reasonable” Amount of Builds
Review: Building out the WECC to Regional Reserve Margins

• Before we can run prices, we need to simulate likely plant buildout in all of the WECC.

• Key reasons to build.

1. **Planning Reserve Margins for each reserve sharing group.**
   - Southwest Reserve Sharing Group
   - Rocky Mountain Reserve Sharing Group
   - California ISO (includes part of Baja California)
   - Northwest Power Pool US
   - Northwest Power Pool Canada

2. **WECC clean and RPS policy levels.**

3. **Peaking/Reserves Capability/Need Timing**
Recent Planning Shows More Builds

- Way more discussion of role of EE and DR as important in deferring builds throughout WECC planning.
- Resource plans released before current round of policies (<20 GW)
  - PNM and El Paso Electric plan for 2.2 GW nameplate/delivered of renewables by 2035
  - Xcel planning for 2.5 GW nameplate by 2035
    (1.8 GW of renewables and .3 GW of storage and .4 GW of gas)
  - BC Hydro building Site C (1.1 GW) and AESO contracted 1.5 GW of wind and has planned conversions of at least 2 GW of coal to gas
    (13 GW of new or converted gas planned before 2039)
  - Tri-State has a very dated plan but has many impending retirements
- Resource plans finalized after current round of policies (~180 GW)
  - CEC plans for 144 GW nameplate by 2045 reference case
    (90 GW Renewables, 50 GW Batteries, 4 GW Pumped Storage)
  - Pacificorp and NV Energy plan for 17 GW nameplate by 2045
    (13.6 GW Renewables, 3.4 GW Storage)
  - APS, Tucson Energy and SRP plan for 18.5 GW nameplate/delivered by 2035
    (11.9 GW of renewables, 6.6 GW of storage)
Review Case Study: LADWP

How much can we really trust our ‘back of the envelope’ calculations or gut?
Why Hoping for a Build Less Than 300 MW is Probably Optimistic.

Example: Using LADWP load and solar without other resources or market help

Seasonal/Daily Needs Versus Capability Creates Solar Oversupply

- Charge storage with excess solar
- Discharge storage where storage does not cover load

24 to 26 GW nameplate to cover a peak of 6641 MW
So Diversity Helps, Is It Available?

Here market reliance saves money, but where is it coming from? Does another region build?

In 2025, diverse market sources NW, Mountain West, SW...

In 2045, more reliance on NW...
Wind into LA in AURORA

- Seems like not all the transmission import capability is utilized.
- Why not reduce solar/storage strategy more by accessing nearby wind resources?
  - CA and SW maxed out on wind per current transmission
  - NW wind would have to displace NW hydro, especially in spring
  - Wyoming and New Mexico wind needs transmission expansion
LA Review: Sun, More Sun, Storage and Curtailment midday

- Unless there is more transmission in the rest of the WECC,
- And wind resources are sufficiently high enough in capacity factor to the storage and more solar,
- We should likely not be surprised by the following:

1. Upwards of **50% curtailment of solar** at the end of the study in places with a large solar and solar/battery buildout
2. The battery build will be at least **twice** the need and the solar will be **four** times the need.
3. Fixed cost investment will probably be order of magnitude **6 times** more than just building baseload gas.

- Effects of demand response, BTM solar/storage and effects on transmission and distribution.

Note that LADWP has done some comprehensive work on this topic at the following link: [LA 100](#)
New “Back of Envelope” look
Data Updates, Load Diversity and Renewable Curtailments
Resource Planning 201:
How Much Do We Need to Build? The fancier version...

• After the CA and AZ demand forecast adjustments...
1. Since there is uncertainty around demand and supply, we add a reserve margin.
   • Reserve Margins in the WECC are between 11% and 17% (**15.5%** weighted average by peak load)
2. Coincident load and peak load has traditionally increased over time to some extent, but not as much as non-coincident load.
   • Coincident peak load in the WECC forecasted to go from 143 GW in 2021 to 177 GW in 2045 (approximately **34 GW** of peak load growth)
   • Non-coincident peak load in the WECC forecasted to go from 177 GW in 2021 to 229 GW in 2045 (approximately **52 GW** of peak load growth)
3. Assuming everyone has planned to reserve margins, we need at least **34 GW * (1 + 0.155) = 39 GW of peak load**
Resource Planning 201: What to Expect from a Buildout?

- How do we balance demand with supply?
- Average demand increases from 100 aGW to 127 aGW

1. Existing resources are periodically retired and need to be replaced
   - Approximately 31 GW (after approx. 10% scheduled and unscheduled outages 28 aGW) of retirements between 2021 and 2045, and 9 GW from 2018 to 2020

2. New resource options do not replace resource peak MW ($39+31 = 70$ GW need) and average MW ($27+28 = 53$ aGW need) on a 1-1 basis.
Power Planning 201: The Planner’s Nightmare

• Mandates change what can be built and where
  • Between 2021 and 2045, an additional 15 aGW qualifying resources to meet RPS policies, respectively.
  • In 2021, the WECC starts out with 42-ish aGW of qualifying clean resources and is trying to meet 105 aGW by the end of the study to meet clean policies. (So 63 aGW more for those who are still counting..)
  • More issues from losses, forced renewable curtailments and other transmission constraints depending on siting
  • More diversity in resource pools helps, even with the transmission considerations, so smaller reserve pools may increase overall need.

• Since the clean requirement need is higher than the energy need (63 aGW > 53 aGW), let’s just use 63 aGW as a proxy for our energy need calculations
### Calculating Nameplate Need*

<table>
<thead>
<tr>
<th></th>

<td>10%</td>
<td>.25%</td>
</tr>
<tr>
<td>Energy</td>
<td>20%</td>
<td>25%</td>
<td>33%</td>
<td>88% efficient</td>
</tr>
<tr>
<td>Peak Load + PRM + Retirements MW</td>
<td>(70 \div .25 = 280 \text{ GW})</td>
<td>(70 \div .33 = 210 \text{ GW})</td>
<td>(70 \div .1 = 700 \text{ GW})</td>
<td>(70 \div .25 = 280 \text{ GW})</td>
</tr>
<tr>
<td>Clean/RPS requirements</td>
<td>(63 \div .2 = 315 \text{ GW})</td>
<td>(63 \div .25 = 252 \text{ GW})</td>
<td>(63 \div .33 = 189 \text{ GW})</td>
<td></td>
</tr>
</tbody>
</table>

Higher CA load forecast and decrease in AZ forecast changes the calculations...

Seems like between 252 and 315 GW buildout should not be too surprising...
WECC is adequate to a 15% PRM under *average hydro* conditions, but we try to plan to considering difficult hydro conditions.

- Assumption that WECC was adequate to a 15% PRM is short by approximately 10 GW (based on capability per low hydro conditions and transmission losses)
- Peak +PRM need before was 70 GW, now goes up by 10 GW for current capability shortage gets us to approximately 80 GW by the end of the study

Solar buildouts at the sizes we are talking about usually result in at least 50% *curtailment* by the end of the study

- With solar and solar plus battery strategy heavy builds we have been seeing significant curtailment even when more storage is associated.

<td></td>
</tr>
</tbody>
</table>

If only it could be simpler, now we are between 504 GW and 630 GW nameplate buildout ...
How Does all this Guide an Instinct for Overall Build Size?

• Knowing that there are transmission limitations but also resource diversity, per the LADWP example, AURORA should still be able to reduce the renewable curtailment by at least 5 to 10%.

• If renewable curtailment can be reduced by 10% our range would then be 420 GW to 525 GW.

Good news! We have multiple options from 429 GW to 437 GW.
Review Recent Findings and Methodology Changes

Updated buildouts, methodology improvements
Tried 3 Changes since 10/22: 2 out of 3 Methods Improved Result

- Knowing the SAAC was tentatively OK with the build from last time as a backstop. Staff attempted three improvements of which two were fairly successful.
  1. Calculated the REC cost using shadow prices and an adequate system in AURORA.
     - REC cost at 8 $/MWh was still producing many curtailments.
  2. Assigned CA the firm imports ramping up per draft SB100 analysis.
     - Solved the PRM and price disconnect.
  3. Attempted a simulation with increased transmission.
     - This did not reduce overall buildout as much as hypothesized.
Calculation of REC Price from AURORA

1. Ensure an adequate system.
   • Setup AURORA with unlimited simple cycle plants with no fixed costs.

2. Do a long-term buildout with no REC pricing.

3. See shadow price (in $/MWh) of meeting the RPS constraint in the model.

4. This should be better tuned to ensure enough energy is produced to meet long-term RPS/Clean constraints.

This may be useful/necessary for RPM work as well!

Solar and gas builds go down and wind builds go up. Overall build size is 8 GW less. Build is deferred to later in study.
Adequate system throughout WECC, but due to renewable energy curtailment does not meet clean requirement in every year.

For comparison, WECC nameplate capacity installed in 2021.
Meeting Clean Policy Requirements Until Late 2030’s With Less Overbuilds

This is smaller than in a less diverse portfolio
Close to 180 GW build from **SB 100 draft work**, biggest difference BTM solar and out of state wind.
Arizona and New Mexico backfilling for significant coal retirements and building for California and New Mexico clean policy
Nevada, Wyoming, Colorado, and Utah backfilling for significant coal retirements provide some diversity to the CA and Desert SW builds.
All but 4 GW of natural gas builds in Alberta or Baja CA.

Both have fairly immediate needs and limited resource and transmission options.
NW has modest investments mostly in flexibility and capacity that complement the hydro system and energy surplus elsewhere.
Fixed costs more than 6 times production costs for WECC, NWPP fixed and production costs stay similar.
Average prices over the year can be misleading, and are driven by the solar oversupply mid-day. Prices in CA and Desert SW can be significantly higher during the evening ramp and even during nighttime through early morning hours.
1. General support for the buildout as a baseline scenario.
   - Some folks believe that a smaller buildout will be more likely with more gas, alternative resource types and/or alternative compliance with clean policies.

2. Lots of builds in the first 5 years, will they show up?
   - Perhaps do some studies to understand this risk on the adequacy side.

3. Increase coordination with planning processes WECC-wide.
   - Specifically associated with transmission, demand-side and BTM plans for WECC utilities
Mid-C Price and Avoided Emissions Rate Data

Limited results for the Baseline buildout

*We will be looking at power prices over different climate change sets and weather conditions...*
Inflection points are changes in decadal hydro conditions.
Seasonal Variation Increases Over Time
Persistent low pricing in spring and late winter. Throughout climate change record more NW hydro in the winter pushes down prices.
Prices are higher in summer consistently. Throughout climate change record less NW hydro in the summer raises prices.
Daily shape changes with more WECC-wide solar
Seasonal daily shapes by 2026 have low mid-day pricing and peaky ramps
Prices by 2041 have persistent negative pricing seasonally for many hours mid-day.
Market Price Conclusions

More Price Spread in RPM
- RPM also looks at different gas price scenarios
- Those simulations are still running...

Daily Price Shape is Important
- Net peak driving prices more than peak.
- Resources that must run midday will be competing with extremely low market prices
- Maintaining reserves and ramping capability while undergoing persistent negative price periods could be a challenge for the WECC, and by the end of the study the NW.
- Resources with ramping capability with low must-run requirements will be more and more valuable.
- Hydro conditions still the major driver of price variability at Mid-C.
Avoided Market Emissions Rate Decreases Over Time

Annual Avoided CO2 and CO2e in lbs per kWh

</table>
Higher emissions avoidance during summer during WECC peak.

Avoided emissions rate increases slightly in summer, but decreases overall.
Lower Market Emissions Rate
Implications: RPM Preview

• In recent studies, the market emissions rate has been closer to a combined cycle, 0.8 to 0.9 lbs per kWh.

• Recall, we are quantifying emissions damage costs in the RPM.

• When market emissions rates drop below emissions rates of existing regional resources, the market will likely start to displace the dispatch of some of the higher emitting existing regional resources to reduce overall costs.
Next Steps

1. Use buildout to guide GENESYS market hourly capability for adequacy work.

2. Develop quarterly and intra-quarterly price information for RPM to use as starting point for the baseline scenario.

3. Develop avoided emissions information for the RPM for the baseline scenario.

4. Begin working on additional AURORA buildouts for other scenarios/sensitivities.
   • Market reliance
   • Organized/limited markets
   • Early retirements
   • ???
Additional Slides
Addition of Transmission

- Explore whether transmission limitations was significantly impacting build size or diversity.

1. Tested 1500 MW additional capability into NW from Wyoming.

2. Tested 1500 MW additional capability into California from Wyoming.

3. Increased possible wind from New Mexico that could sink to Desert SW load, but only make it to California with existing transport between regions.

This buildout test is referred to as the “With Transmission Additions”
### Limited Gas per Regulatory and Policy Climate (October 28, 2020)

</table>

*Build is deferred to later in study. Slightly more wind is built in WY and almost all available in NM, but overall build is closer to 10/21 build. Overall narrative similar.*
Disclaimer!

- Since the run with transmission additions did not yield significantly different results, the following information will be describing the build **without** additional transmission.

- Staff suggests if exploration of transmission additions is desirable, it could be explored via scenario analysis.

Buildout Notes

- Regional energy efficiency is assumed to continue at 7th Power Plan price levels (using new supply curve ramp and shaping data).
  - Over 900 aMW by 2025 and over 4000 aMW by 2041

- AURORA did not have the capability of building new demand response, and significant demand response is below 4 hour battery investment levels.
